

LECTURE 15

LECTURE OUTLINE

- Problem Structures
 - Separable problems
 - Integer/discrete problems – Branch-and-bound
 - Large sum problems
 - Problems with many constraints
- Conic Programming
 - Second Order Cone Programming
 - Semidefinite Programming

SEPARABLE PROBLEMS

- Consider the problem

$$\begin{aligned} & \text{minimize} && \sum_{i=1}^m f_i(x_i) \\ \text{s. t.} &&& \sum_{i=1}^m g_{ji}(x_i) \leq 0, \quad j = 1, \dots, r, \quad x_i \in X_i, \quad \forall i \end{aligned}$$

where $f_i : \mathfrak{R}^{n_i} \mapsto \mathfrak{R}$ and $g_{ji} : \mathfrak{R}^{n_i} \mapsto \mathfrak{R}$ are given functions, and X_i are given subsets of \mathfrak{R}^{n_i} .

- Form the dual problem

$$\text{maximize} \quad \sum_{i=1}^m q_i(\mu) \equiv \sum_{i=1}^m \inf_{x_i \in X_i} \left\{ f_i(x_i) + \sum_{j=1}^r \mu_j g_{ji}(x_i) \right\}$$

subject to $\mu \geq 0$

- **Important point:** The calculation of the dual function has been **decomposed** into n simpler minimizations. Moreover, the calculation of dual subgradients is a **byproduct of these minimizations** (this will be discussed later)

- **Another important point:** If X_i is a discrete set (e.g., $X_i = \{0, 1\}$), the dual optimal value is a lower bound to the optimal primal value. It is still useful in a branch and bound scheme.

LARGE SUM PROBLEMS

- Consider cost function of the form

$$f(x) = \sum_{i=1}^m f_i(x), \quad m \text{ is very large,}$$

where $f_i : \mathfrak{R}^n \mapsto \mathfrak{R}$ are convex. Some examples:

- **Dual cost of a separable problem.**
- **Data analysis/machine learning:** x is parameter vector of a model; each f_i corresponds to error between data and output of the model.
 - Least squares problems (f_i quadratic).
 - ℓ_1 -regularization (least squares plus ℓ_1 penalty):

$$\min_x \sum_{j=1}^m (a'_j x - b_j)^2 + \gamma \sum_{i=1}^n |x_i|$$

The nondifferentiable penalty tends to set a large number of components of x to 0.

- **Min of an expected value** $E\{F(x, w)\}$, where w is a random variable taking a finite but very large number of values w_i , $i = 1, \dots, m$, with corresponding probabilities π_i .

- **Stochastic programming:**

$$\min_x \left[F_1(x) + E_w \left\{ \min_y F_2(x, y, w) \right\} \right]$$

- Special methods, called **incremental** apply.

PROBLEMS WITH MANY CONSTRAINTS

- Problems of the form

$$\begin{aligned} & \text{minimize} && f(x) \\ & \text{subject to} && a'_j x \leq b_j, \quad j = 1, \dots, r, \end{aligned}$$

where r : very large.

- One possibility is a *penalty function approach*: Replace problem with

$$\min_{x \in \mathbb{R}^n} f(x) + c \sum_{j=1}^r P(a'_j x - b_j)$$

where $P(\cdot)$ is a scalar penalty function satisfying $P(t) = 0$ if $t \leq 0$, and $P(t) > 0$ if $t > 0$, and c is a positive penalty parameter.

- Examples:
 - The quadratic penalty $P(t) = (\max\{0, t\})^2$.
 - The nondifferentiable penalty $P(t) = \max\{0, t\}$.
- Another possibility: Initially discard some of the constraints, solve a less constrained problem, and later reintroduce constraints that seem to be violated at the optimum (*outer approximation*).
- Also *inner approximation* of the constraint set.

CONIC PROBLEMS

- A conic problem is to minimize a convex function $f : \Re^n \mapsto (-\infty, \infty]$ subject to a cone constraint.
- The most useful/popular special cases:
 - Linear-conic programming
 - Second order cone programming
 - Semidefinite programming

involve minimization of a linear function over the intersection of an affine set and a cone.

- Can be analyzed as a special case of Fenchel duality.
- There are many interesting applications of conic problems, including in discrete optimization.

PROBLEM RANKING IN INCREASING PRACTICAL DIFFICULTY

- Linear and (convex) quadratic programming.
 - Favorable special cases.
- **Second order cone programming.**
- **Semidefinite programming.**
- Convex programming.
 - Favorable special cases.
 - Geometric programming.
 - Quasi-convex programming.
- Nonlinear/nonconvex/continuous programming.
 - Favorable special cases.
 - Unconstrained.
 - Constrained.
- Discrete optimization/Integer programming
 - Favorable special cases.

CONIC DUALITY

- Consider minimizing $f(x)$ over $x \in C$, where $f : \mathfrak{R}^n \mapsto (-\infty, \infty]$ is a closed proper convex function and C is a closed convex cone in \mathfrak{R}^n .
- We apply Fenchel duality with the definitions

$$f_1(x) = f(x), \quad f_2(x) = \begin{cases} 0 & \text{if } x \in C, \\ \infty & \text{if } x \notin C. \end{cases}$$

The conjugates are

$$f_1^*(\lambda) = \sup_{x \in \mathfrak{R}^n} \{ \lambda'x - f(x) \}, \quad f_2^*(\lambda) = \sup_{x \in C} \lambda'x = \begin{cases} 0 & \text{if } \lambda \in C^*, \\ \infty & \text{if } \lambda \notin C^*, \end{cases}$$

where $C^* = \{ \lambda \mid \lambda'x \leq 0, \forall x \in C \}$ is the polar cone of C .

- The dual problem is

$$\begin{aligned} & \text{minimize} && f^*(\lambda) \\ & \text{subject to} && \lambda \in \hat{C}, \end{aligned}$$

where f^* is the conjugate of f and

$$\hat{C} = \{ \lambda \mid \lambda'x \geq 0, \forall x \in C \}.$$

$\hat{C} = -C^*$ is called the *dual* cone.

LINEAR-CONIC PROBLEMS

- Let f be affine, $f(x) = c'x$, with $\text{dom}(f)$ being an affine set, $\text{dom}(f) = b + S$, where S is a subspace.
- The primal problem is

$$\begin{aligned} & \text{minimize} && c'x \\ & \text{subject to} && x - b \in S, \quad x \in C. \end{aligned}$$

- The conjugate is

$$\begin{aligned} f^*(\lambda) &= \sup_{x-b \in S} (\lambda - c)'x = \sup_{y \in S} (\lambda - c)'(y + b) \\ &= \begin{cases} (\lambda - c)'b & \text{if } \lambda - c \in S^\perp, \\ \infty & \text{if } \lambda - c \notin S^\perp, \end{cases} \end{aligned}$$

so the dual problem can be written as

$$\begin{aligned} & \text{minimize} && b'\lambda \\ & \text{subject to} && \lambda - c \in S^\perp, \quad \lambda \in \hat{C}. \end{aligned}$$

- The primal and dual have the same form.
- If C is closed, the dual of the dual yields the primal.

SPECIAL LINEAR-CONIC FORMS

$$\min_{Ax=b, x \in C} c'x \quad \iff \quad \max_{c-A'\lambda \in \hat{C}} b'\lambda,$$

$$\min_{Ax-b \in C} c'x \quad \iff \quad \max_{A'\lambda=c, \lambda \in \hat{C}} b'\lambda,$$

where $x \in \mathbb{R}^n$, $\lambda \in \mathbb{R}^m$, $c \in \mathbb{R}^n$, $b \in \mathbb{R}^m$, $A : m \times n$.

- For the first relation, let x be such that $Ax = b$, and write the problem on the left as

$$\begin{aligned} & \text{minimize} && c'x \\ & \text{subject to} && x - x \in N(A), \quad x \in C \end{aligned}$$

- The dual conic problem is

$$\begin{aligned} & \text{minimize} && x'\mu \\ & \text{subject to} && \mu - c \in N(A)^\perp, \quad \mu \in \hat{C}. \end{aligned}$$

- Using $N(A)^\perp = \text{Ra}(A')$, write the constraints as $c - \mu \in -\text{Ra}(A') = \text{Ra}(A')$, $\mu \in \hat{C}$, or

$$c - \mu = A'\lambda, \quad \mu \in \hat{C}, \quad \text{for some } \lambda \in \mathbb{R}^m.$$

- Change variables $\mu = c - A'\lambda$, write the dual as

$$\begin{aligned} & \text{minimize} && x'(c - A'\lambda) \\ & \text{subject to} && c - A'\lambda \in \hat{C} \end{aligned}$$

discard the constant $x'c$, use the fact $Ax = b$, and change from min to max

SOME EXAMPLES

- **Nonnegative Orthant:** $C = \{x \mid x \geq 0\}$.
- **The Second Order Cone:** Let

$$C = \left\{ (x_1, \dots, x_n) \mid x_n \geq \sqrt{x_1^2 + \dots + x_{n-1}^2} \right\}$$

- **The Positive Semidefinite Cone:** Consider the space of symmetric $n \times n$ matrices, viewed as the space \mathfrak{R}^{n^2} with the inner product

$$\langle X, Y \rangle = \text{trace}(XY) = \sum_{i=1}^n \sum_{j=1}^n x_{ij} y_{ij}$$

Let C be the cone of matrices that are positive semidefinite.

- All these are *self-dual*, i.e., $C = -C^* = \hat{C}$.

SECOND ORDER CONE PROGRAMMING

- Second order cone programming is the linear-conic problem

minimize $c'x$

subject to $A_i x - b_i \in C_i, i = 1, \dots, m,$

where c, b_i are vectors, A_i are matrices, b_i is a vector in \mathbb{R}^{n_i} , and

C_i : the second order cone of \mathbb{R}^{n_i}

- The cone here is

$$C = C_1 \times \dots \times C_m$$

SECOND ORDER CONE DUALITY

- Using the generic special duality form

$$\min_{Ax-b \in C} c'x \quad \iff \quad \max_{A'\lambda=c, \lambda \in \hat{C}} b'\lambda,$$

and self duality of C , the dual problem is

$$\begin{aligned} \text{maximize} \quad & \sum_{i=1}^m b'_i \lambda_i \\ \text{subject to} \quad & \sum_{i=1}^m A'_i \lambda_i = c, \lambda \quad i \in C_i, \quad i = 1, \dots, m, \end{aligned}$$

where $\lambda = (\lambda_1, \dots, \lambda_m)$.

- The duality theory is no more favorable than the one for linear-conic problems.
- There is no duality gap if there exists a feasible solution in the interior of the 2nd order cones C_i .
- Generally, second order cone problems can be recognized from the presence of norm or convex quadratic functions in the cost or the constraint functions.
- There are many applications.

EXAMPLE: ROBUST LINEAR PROGRAMMING

minimize $c'x$

subject to $a'_j x \leq b_j, \quad \forall (a_j, b_j) \in T_j, \quad j = 1, \dots, r,$

where $c \in \Re^n$, and T_j is a given subset of \Re^{n+1} .

- We convert the problem to the equivalent form

minimize $c'x$

subject to $g_j(x) \leq 0, \quad j = 1, \dots, r,$

where $g_j(x) = \sup_{(a_j, b_j) \in T_j} \{a'_j x - b_j\}$.

- For special choice where T_j is an ellipsoid,

$$T_j = \{(a_j + P_j u_j, b_j + q'_j u_j) \mid \|u_j\| \leq 1\}$$

we can express $g_j(x) \leq 0$ in terms of a SOC:

$$\begin{aligned} g_j(x) &= \sup_{\|u_j\| \leq 1} \{(a_j + P_j u_j)'x - (b_j + q'_j u_j)\} \\ &= \sup_{\|u_j\| \leq 1} (P'_j x - q_j)'u_j + a'_j x - b_j, \\ &= \|P'_j x - q_j\| + a'_j x - b_j. \end{aligned}$$

Thus, $g_j(x) \leq 0$ i ff $(P'_j x - q_j, b_j - a'_j x) \in C_j$, where C_j is the SOC.
